

# RESULTS

- 663 enrolled
- 55 randomised
- no significant reduction in number of allogeneic units transfused in the FC vs placebo group
- subgroup analysis suggests that fibrinogen replacement not required if Fibtex A5 is  $>12\text{mm}$  or fibrinogen is  $>2\text{g/L}$

# DISCUSSION

- early infusion of FC of Fibtex  $\leq 15\text{mm}$  did not lead to reduction in transfusion requirements or blood loss
- $>12\text{mm}$  or fib  $>2\text{g/L}$  are adequate for haemostasis
- below this threshold, requires more investigation
- fib  $<2\text{g/L}$  uncommon during PPH
- FIBTEM remained  $>15\text{mm}$  and PT and APTT normal in  $>90\%$  of cases with bleeding controlled w/o haemostatic support - early empirical FFP may be harmful
- fewer than expected randomised with fibrinogen  $<2\text{g/L}$
- 2 thrombotic events, one in each group
